

Preparing the HANDS ON “Sharding Data with MongoDB”

These are instructions concerning the preparation **IN ADVANCE** of the third hands-on Lab on “Data Sharding with MongoDB”.

We are adopting a completely different setting even if we are also using MongoDB. The objective is to show on-line solutions available for working with the store and having a simple experience dealing with cluster like architectures.

Material required

- Computer with a browser
- Internet connection

The concepts used here docker, instance, ... will be explained during the hands-on session.

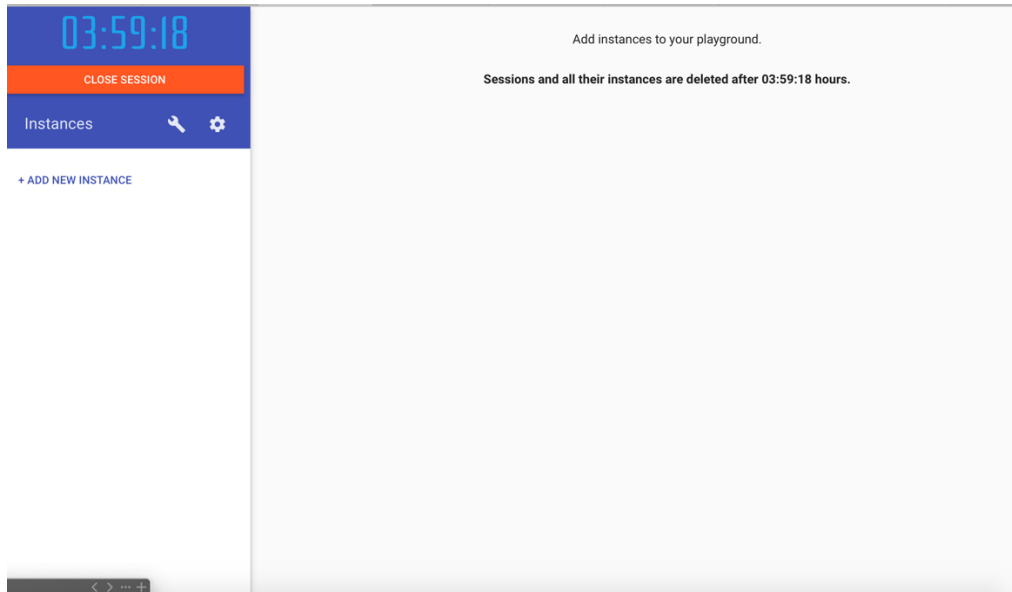

ToDo

We will use the tool “*play with docker*” that provides an ONLINE solution for configuring “virtualized” computing environments using a browser.

1. Create an account on <https://hub.docker.com/>
2. Go to play-with-docker.com. You will see the following page. Click on start. Enter your docker hub credentials if asked.

- Having clicked on the **green button start** you will land in the following page. It will provide you with a virtual execution environment in which you will execute commands on a shell.

- In order to create this execution environment, click on **+ ADD NEW INSTANCE** in the left part of the page. By clicking you are creating a virtual execution space that provides you with computing resources as if you were on another computer.

This instance has 4 hours lifetime and all data is deleted after that.
